🏷️ Tags	

Thank you for your interest in working at Speakeasy. We would love it if you could complete the following take home assignment. We would like you to build a reasonably ambitious React component modelled off DataDog's log browser, in particular their fuzzy search UI input component.

If you've used DataDog before this might be familiar to you, but if it isn't, the video below demonstrates what we'd like you to build:

[attachment:83189b20-1cc1-4777-b5da-b03f1a4148c7:CleanShot_2025-07-03_at_17.31.20.mp4](#)

Your solution should cover the main interactions demonstrated in the video. The key elements are:

- Typing the name of a known "facet" such as `service` followed by a colon (`:`) should result in the input's dropdown showing all of the known unique values for that particular facet.

- Once you have entered “unique value mode”, using your `up` / `down` arrow keys should highlight the relevant value
- Pressing the Enter key (or clicking) on a particular facet value should result in the tag being “completed” and added to the input as a completed tag.
- Once a tag has been “completed”, the input should be cleared so you can add more facet/tags to the query.
- The combination of facets/tags in the query should filter the data in the table (we have setup a basic table for you in the template repo linked below)

What we are looking for:

- Functionally, the solution should work well, and you should be able to use the component entirely with your keyboard OR your mouse
- We want you to make it look pretty! You can make it look like the DataDog component, or how you’d like it to look :)
- This is an opportunity to show some creativity - there is no one right solution to this problem, so if you don’t like some aspect of the interaction or the style of the UI component, feel free to change it.
- We’d like you to show some consideration for how this component might be productionized, or at least be able to allude to it in the review session (e.g this component will be driven by client side data, but in production there might be millions of logs and many facets).

We have setup a template repo that sets up some basic details that will help get you started, including some sample data modelled on the concept of a `HttpLog` interface (we’ve defined some sample properties such as `method` and `status` that will serve as your facets). You can find that template repo at <https://github.com/speakeasy-api/frontend-test-template>.

We have setup Tailwind in the repo, but you are welcome to use any CSS technology you wish, and additionally any JavaScript libraries that you feel will assist you. Furthermore, you are welcome to use any AI tooling you wish to complete the task, but please call out if you have done so in the README.
